

# VK Multimedia Information Systems

Mathias Lux, [mlux@itec.uni-klu.ac.at](mailto:mlux@itec.uni-klu.ac.at)

# Information Retrieval Basics: Agenda

- **Vector Retrieval Model**
  - Exercise 01
- Other Retrieval Models
- Common Retrieval Methods
  - Query Modification
  - Co-Occurrence
  - Relevance Feedback
- Exercise 02

# Vector Model

- Integrates the notion of partial match
- Non-binary weights (terms & queries)
- Degree of similarity computed

$$\vec{d}_j = (w_{1,j}, w_{2,j}, \dots, w_{t,j})$$

$$\vec{q} = (w_{1,q}, w_{2,q}, \dots, w_{t,q})$$

# Vector model: Similarity

$$\text{sim}(d_j, q) = \frac{\vec{d}_j \bullet \vec{q}}{|\vec{d}_j| \times |\vec{q}|} = \frac{\sum_{i=1}^t w_{i,j} \cdot w_{i,q}}{\sqrt{\sum_{i=1}^t w_{i,j}^2} \cdot \sqrt{\sum_{i=1}^t w_{i,q}^2}}$$

# Vector Model: Example

$$\vec{d} = (0.3, 0.4, 0, 0.1, 1)$$

$$\vec{q} = (1, 0, 0, 0.5, 0)$$

$$\text{sim}(\vec{d}, \vec{q}) = \frac{1 \cdot 0.3 + 0.1 \cdot 0.5}{\sqrt{0.3^2 + 0.4^2 + 0.1^2 + 1} \cdot \sqrt{1 + 0.5^2}} \approx \frac{0.35}{2.24} \approx 0.17$$

# Another Example:

- Document & Query:

- D = “The quick brown fox jumps over the lazy dog”
- Q = “brown lazy fox”

$$\text{sim}(d_j, q) = \frac{\vec{d}_j \cdot \vec{q}}{|\vec{d}_j| \times |\vec{q}|} = \frac{\sum_{i=1}^t w_{i,j} \cdot w_{i,q}}{\sqrt{\sum_{i=1}^t w_{i,j}^2} \cdot \sqrt{\sum_{i=1}^t w_{i,q}^2}}$$

- Results:

- $(1,1,1,1,1,1,1,2)^t * (1,1,1,0,0,0,0,0)^t = 3$
- $\text{sqrt}(12) * \text{sqrt}(3) = \dots$
- Similarity =  $3 / \dots$

# Term weighting: TF\*IDF

Term weighting increases retrieval performance

- Term frequency
  - How often does a term occur in a document?
  - Most intuitive approach
- Inverse Document Frequency
  - What is the information content of a term for a document collection?
  - Compare to *Information Theory* of Shannon

# Example: IDF

## 300 documents corpus

# Definitions: Normalized Term Frequency

$$f_{i,j} = \frac{freq_{i,j}}{\max_l(freq_{l,j})} \dots \text{normalized term frequency}$$

$freq_{i,j}$  ... raw term frequency of term  $i$  in document  $j$

- Maximum is computed over all terms in a document
- Terms which are not present in a document have a raw frequency of 0

# Definitions: Inverse Document Frequency

$idf_i = \log \frac{N}{n_i}$  ... inverse document frequency for term  $i$

$N$  ... number of documents in the corpus

$n_i$  ... number of document in the corpus which contain term  $i$

- Note that  $idf_i$  is independent from the document.
- Note that the whole corpus has to be taken into account.

# Why log(...) in IDF?

# TF\*IDF

- TF\*IDF is a very prominent weighting scheme
  - Works fine, much better than TF or Boolean
  - Quite easy to implement

$$w_{i,j} = f_{i,j} \cdot \log \frac{N}{n_i}$$

# Weighting of query terms

$$w_{i,q} = \left(0.5 + \frac{0.5 \cdot f_{i,q}}{\max_l(f_{l,q})}\right) \cdot \log \frac{N}{n_i}$$

- Also using IDF of the corpus
- But TF is normalized differently
  - TF > 0.5
- Note: the query is not part of the corpus!

# Vector Model

- Advantages
  - Weighting schemes improve **retrieval performance**
  - Partial matching allows retrieving documents that **approximate query** conditions
  - Cosine coefficient allows **ranked list** output
- Disadvantages
  - Term are assumed to be mutually independent

# Simple example (i)

- Scenario
  - Given a **document corpus on birds**: nearly each document (say 99%) contains the word bird
  - someone is searching for a document about sparrow nest construction with a query “**sparrow bird nest construction**”
  - Exactly the document which would satisfy the user needs **does not have the word “bird”** in it.

# Simple example (ii)

- TF\*IDF weighting
  - knows upon the low discriminative power of the term bird
  - The weight of this term is near to zero
  - This term has virtually no influence on the result list.

# Information Retrieval Basics: Agenda

- Vector Retrieval Model
  - **Exercise 01**
- Other Retrieval Models
- Common Retrieval Methods
  - Query Modification
  - Co-Occurrence
  - Relevance Feedback
- Exercise 03

# Exercise 01

- Given a document collection ...
- Find the results to a query ...
  - Employing the Boolean model
  - Employing the vector model (with  $TF*IDF$ )
- Some hints:
  - Excel:
    - Sheet on homepage
    - Use functions “Summenprodukt” & “Quadratesumme”

# Exercise 01

- Document collection (6 documents)
  - spatz, amsel, vogel, drossel, fink, falke, flug
  - spatz, vogel, flug, nest, amsel, amsel, amsel
  - kuckuck, nest, nest, ei, ei, ei, flug, amsel, amsel, vogel
  - amsel, elster, elster, drossel, vogel, ei
  - falke, katze, nest, nest, flug, vogel
  - spatz, spatz, konstruktion, nest, ei
- Queries:
  - spatz, vogel, nest, konstruktion
  - amsel, ei, nest

# Exercise

	d1	d2	d3	d4	d6	d6	idf
amsel	1	3	2	1			
drossel	1			1			
ei			3	1		1	
elster				2			
falke	1				1		
fink	1						
flug	1	1	1		1		
katze					1		
konstruktion						1	
kuckuck			1				
nest		1	2		2	1	
spatz	1	1				2	
vogel	1	1	1	1	1		

# Information Retrieval Basics: Agenda

- Vector Retrieval Model
  - Exercise 01
- **Other Retrieval Models**
- Common Retrieval Methods
  - Query Modification
  - Co-Occurrence
  - Relevance Feedback
- Exercise 02

# Other Retrieval Models: Set Theoretic Models

- Fuzzy Set Model
  - Each query term defines a fuzzy set
  - Each document has a **degree of membership**
  - Done e.g. with query expansion (co-occurrence or thesaurus)
- Extended Boolean Model
  - Incorporates non binary weights
  - Geometric interpretation: Distance between document vector and desired Boolean state (query)

# Algebraic Models: Generalized Vector Space $M$ .

- Term independence not necessary
- Terms (as dimensions) are not orthogonal and may be linear dependent.
- Smaller linear independent units exist.
  - $m$  ... minterm
  - Constructed from co-occurrence:  $2^t$  minterms
- Dimensionality a problem
  - Number of active minterms (which actually occur in a document)
  - Depends on the number of documents

# Algebraic Models: Latent Semantic Indexing M.

- Introduced 1988, LSI / LSA
- Concept matching vs. term matching
- Mapping documents & terms to concept space:
  - Fewer dimensions
  - Like clustering

# Algebraic Models: Latent Semantic Indexing M.

- Let  $M_{ij}$  be the document term matrix
  - with  $t$  rows (terms) and  $N$  cols (docs)
- Decompose  $M_{ij}$  into  $K^*S^*D^t$ 
  - $K$  .. matrix of eigenvectors from term-to-term (co-occurrence) matrix
  - $D^t$  .. matrix of eigenvectors from doc-to-doc matrix
  - $S$  ..  $r \times r$  diagonal matrix of singular values with  $r = \min(t, N)$ , the rank of  $M_{ij}$

# Algebraic Models: Latent Semantic Indexing M.

- With  $M_{ij} = K * S * D^t \dots$
- Only the  $s$  largest singular values from  $S$ :
  - Others are deleted
  - Respective columns in  $K$  and  $D^t$  remain
- $M_s = K_s * S_s * D_s^t \dots$ 
  - $s < r$  is new rank of  $M$
  - $s$  large enough to fit in all data
  - $s$  small enough to cut out unnecessary details

# Algebraic Models: Latent Semantic Indexing M.

- Reduced doc-to-doc matrix:
  - $M_s^t * M_s$  is  $N \times N$  Matrix quantifying the relationship between documents
- Retrieval is based on pseudo-document
  - Let column  $Q$  in  $M_{ij}$  be the query
  - Calculate  $M_s^t * M_s$
  - First row (or column) gives the relevance

# Algebraic Models: Latent Semantic Indexing M.

- Advantages
  - $M$  even more sparse
  - Retrieval on a “conceptual” level
- Disadvantages
  - Doc-to-doc matrix might be quite big
  - Therefore: Processing time

# Example LSA ...

## Example of text data: Titles of Some Technical Memos

- c1: *Human machine interface for ABC computer applications*
- c2: *A survey of user opinion of computer system response time*
- c3: *The EPS user interface management system*
- c4: *System and human system engineering testing of EPS*
- c5: *Relation of user perceived response time to error measurement*
  
- m1: *The generation of random, binary, ordered trees*
- m2: *The intersection graph of paths in trees*
- m3: *Graph minors IV: Widths of trees and well-quasi-ordering*
- m4: *Graph minors: A survey*

# Algebraic Models: Neural Network M. / Associative Retrieval

- Neural Network:
  - Neurons emit signals to other neurons
  - Graph interconnected by synaptic connections
- Three levels:
  - Query terms, terms & documents

# Algebraic Models: Neural Network M. / Associative Retrieval

# Algebraic Models: Neural Network M. / Associative Retrieval

- Query term is “activated”
  - Usually with weight 1
  - Query term weight is used to “weaken” the signal
- Connected terms receive signal
  - Term weight “weakens” the signal
- Connected documents receive signal
  - Different activation sources are “combined”

# Algebraic Models: Neural Network M. / Associative Retrieval

- First round query terms  $\rightarrow$  terms  $\rightarrow$  docs
  - Equivalent to vector model
- Further rounds increase retrieval performance

# Algebraic Models: Neural Network M. / Associative Retrieval

# Information Retrieval Basics: Agenda

- Vector Retrieval Model
  - Exercise 02
- Other Retrieval Models
- Common Retrieval Methods
  - **Query Modification**
  - Co-Occurrence
  - Relevance Feedback
- Exercise 03

# Query Modification

- Query expansion
  - General method to increase either
    - number of results or
    - accuracy
  - Query itself is modified:
    - Terms are added (co-occurrence, thesaurii)

# Query Expansion

- Integrate existing knowledge
  - Taxonomies
  - Ontologies
- Modify query
  - Related terms
  - Narrower terms
  - Broader terms

# Term Reweighting

- To improve accuracy of ranking
- Query term weights are changed
  - Note: no terms are added / removed
  - Result ranking changes

# Information Retrieval Basics: Agenda

- Vector Retrieval Model
  - Exercise 02
- Other Retrieval Models
- Common Retrieval Methods
  - Query Modification
  - **Co-Occurrence**
  - Relevance Feedback
- Exercise 03

# Co-Occurrence

- Quantify relations between terms
  - Based on how often they occur together
  - Not based on the position
- Let  $M_{ij}$  be the document term matrix
  - with  $t$  rows (terms) and  $N$  cols (docs)
- $M^*M^t$  is the “co-occurrence” matrix

# Co-Occurrence: Example

	d1	d2	d3	d4	d5
computer	7	7	0	8	3
pda	5	1	4	0	3
cellphone	0	1	5	0	0
wlan	6	1	0	0	4
network	1	2	0	6	0

7	5	0	6	1
7	1	1	1	2
0	4	5	0	0
8	0	0	0	6
3	3	0	4	0

# Co-Occurrence: Example

	computer	pda	cellphone	wlan	network
computer	171	51	7	61	69
pda	51	51	21	43	7
cellphone	7	21	26	1	2
wlan	61	43	1	53	8
network	69	7	2	8	41

# Co-Occurrence & Query Expansion

	computer	pda	cellphone	wlan	network
computer	171	51	7	61	69
pda	51	51	21	43	7
cellphone	7	21	26	1	2
wlan	61	43	1	53	8
network	69	7	2	8	41

Query: *cellphone*

Query: *cellphone OR pda*

# Information Retrieval Basics: Agenda

- Vector Retrieval Model
  - Exercise 02
- Other Retrieval Models
- Common Retrieval Methods
  - Query Modification
  - Co-Occurrence
  - **Relevance Feedback**
- Exercise 03

# Relevance Feedback

- Popular Query Reformulation Strategy:
  - User gets list of docs presented
  - User marks relevant documents
  - Typically ~10-20 docs are presented
  - Query is refined, new search is issued
- Proposed Effect:
  - Query moves more toward relevant docs
  - Away from non relevant docs
  - User does not have to tune herself

# Relevance Feedback

- $D_r \subset D$  ... set of relevant docs identified by the user
- $D_n \subset D$  ... set of non relevant docs
- $C_r \subset D$  ... set of relevant docs
- $\alpha, \beta, \gamma$  ... tuning parameters

# Relevance Feedback

- Considering an optimal query
  - Unlikely and therefore hypothetical
- Which vector retrieves  $C_r$  best?

$$\vec{q}_{OPT} = \frac{1}{|C_r|} \cdot \sum_{\forall \vec{d}_j \in C_r} \vec{d}_j - \frac{1}{N - |C_r|} \cdot \sum_{\forall \vec{d}_j \notin C_r} \vec{d}_j$$

# Relevance Feedback

$$\text{Rocchio: } \vec{q}_m = \alpha \cdot \vec{q} + \frac{\beta}{|D_r|} \cdot \sum_{\forall \vec{d}_j \in D_r} \vec{d}_j - \frac{\gamma}{|D_n|} \cdot \sum_{\forall \vec{d}_j \in D_n} \vec{d}_j$$

$$\text{Ide: } \vec{q}_m = \alpha \cdot \vec{q} + \beta \cdot \sum_{\forall \vec{d}_j \in D_r} \vec{d}_j - \gamma \cdot \sum_{\forall \vec{d}_j \in D_n} \vec{d}_j$$

$$\text{Ide-Dec-Hi: } \vec{q}_m = \alpha \cdot \vec{q} + \beta \cdot \sum_{\forall \vec{d}_j \in D_r} \vec{d}_j - \gamma \max_{\text{non-relevant}}(\vec{d}_j)$$

# Relevance Feedback

- Rochio
  - Based on  $q_{OPT}$ ,  $\alpha$  was 1 in original idea
- Ide
  - $\alpha = \beta = \gamma = 1$  in original idea
- Ide-Dec-Hi
  - $\max_{\text{non-relevant}} \dots$  highest ranked doc of  $D_n$
- All three techniques yield similar results ...

# Relevance Feedback

- Evaluation issues:
  - Boosts retrieval performance
  - Relevant documents are ranked top
  - But: Already marked by the user
- Evaluation remains complicated issue

# Information Retrieval Basics: Agenda

- Vector Retrieval Model
  - Exercise 01
- Other Retrieval Models
- Common Retrieval Methods
  - Query Modification
  - Co-Occurrence
  - Relevance Feedback
- **Exercise 02**

# Thanks ...

for your attention!
